

# Detecting Pneumonia in Chest X-Rays

Samuel Rahwa

# Pneumonia Facts

- Pneumonia is a form of acute respiratory infection that affects the lungs.
- Pneumonia accounts for 14% of all deaths of children under 5 years old, killing 740,180 children in 2019
- For US adults, pneumonia is the most common cause of hospital admissions other than women giving birth.
  - About 1 million adults in the US seek care in a hospital due to pneumonia every year, and 50,000 die from this disease

Normal

Bacterial Pneumonia

Viral Pneumonia

It may shock you to learn that the error rate for radiologists is 4%. On average there are 1 billion radiology exams each year. By this logic, that means there will be 40 million radiologist errors.

**Insurance companies frequently request medical records when evaluating claims. What if we could create a system to double check the radiologist's evaluation. This would increase patient safety/long term care and reduce chances of further complications.**

# Source of Data

- Guangzhou Women and Children's Medical Center
  - There are 5,863 X-Ray images (JPEG) and 2 categories (Pneumonia/Normal)
  - Selected from retrospective cohorts of pediatric patients of one to five years old
  - All chest X-ray imaging was performed as part of patients' routine clinical care.
- Provided by Kaggle
  - <https://www.kaggle.com/paultimothymooney/chest-xray-pneumonia>

# EDA (Exploratory Data Analysis)

- Distribution of Images
  - Train Images
    - A total of 5216 Images
  - Test Images
    - A total of 624 Images
- Both Data Sets are Imbalanced
  - Favoring Pneumonia in both cases
- Normal X-Rays are labeled 0
- Pneumonia X-Rays are labeled 1
  - Regardless of the type of pneumonia

# Models

- I went through a four part iterative modeling process and here are the Accuracy Scores
  - Baseline Multilayer Perceptron (MLP), 75 %
  - Baseline Convolutional Neural Network (CNN), 78 %
  - Tuned CNN, (In Progress....still)
  - Transfer Learning CNN, 90 %
- The Transfer Learning CNN was the best model
  - Transfer learning generally refers to a process where a model trained on one problem is used in some way on a second related problem.
    - VGG-16 is a dataset of over 14 million images belonging to 1000 classes
  - One or more layers from the trained model are then used in a new model trained on the pneumonia images.
- The Metrics of the Transfer Learning CNN
  - Roughly 1.87 % of the 624 Images are predicted as normal, when they actually have pneumonia
  - About 7.94 % of the 624 Images are predicted as pneumonia, when they actually are normal
  - The model is accurate at detecting normal and pneumonia cases

Confusion Matrix

# Conclusions

- Insurance companies could use tool to drive down the risks of False Negatives
  - 1.87 % are predicted as normal, when they actually have pneumonia
- By checking the images after receiving a radiologists diagnosis, insurance companies reach out for clarification when they don't come to the same conclusion.

# Next Steps

- We could have doctors and technicians crop out the areas they identify as pneumonia
- Removing the diaphragm in X-Rays, as a standard practice
- Standardizing pixels, resolution and sizes of X-rays images
- Widen the range of ages and geographical distribution of X-Rays Images
- Research more effective tuning methods

# Thank you!
